Spring 2009

Intermediate Formats

for object oriented languages
Program Representation Goals

• Enable Program Analysis and Transformation
  – Semantic Checks, Correctness Checks, Optimizations
• Structure Translation to Machine Code
  – Sequence of Steps

Parse Tree → Semantic Analysis → High Level Intermediate Representation → Low Level Intermediate Representation → Machine Code
High Level IR

- Preserves Object Structure
- Preserves Structured Flow of Control
- Primary Goal: Analyze Program

Low Level IR

- Moves Data Model to Flat Address Space
- Eliminates Structured Control Flow
- Suitable for Low Level Compilation Tasks
  - Register Allocation
  - Instruction Selection
Examples of Object Representation and Program Execution
(This happens when program runs)
class vector {
    int v[ ];

    ... 

    void add(int x) {
        int i;
        i = 0;
        while (i < v.length) {
            v[i] = v[i]+x; i = i+1;
        }
    }
}
Representing Arrays

• Items Stored Contiguously In Memory
• Length Stored In First Word

![Array Representation](3 7 4 8)

• Color Code
  – Red - generated by compiler automatically
  – Blue, Yellow, Lavender - program data or code
  – Magenta - executing code or data
Representing Vector Objects

- First Word Points to Class Information
  - Method Table, Garbage Collector Data
- Next Words Have Object Fields
  - For vectors, Next Word is Reference to Array
Invoking Vector Add Method

vect.add(1);  
- Create Activation Record
Invoking Vector Add Method

vect.add(1);

- Create Activation Record
  - this onto stack
Invoking Vector Add Method

vect.add(1);

- Create Activation Record
  - this onto stack
  - parameters onto stack
Invoking Vector Add Method

vect.add(1);

• Create Activation Record
  – this onto stack
  – parameters onto stack
  – space for locals on stack
Executing Vector Add Method

```java
void add(int x) {
    int i;
    i = 0;
    while (i < v.length)
        v[i] = v[i]+x;
    i = i+1;
}
```
void add(int x) {
    int i;
    i = 0;
    while (i < v.length)
        v[i] = v[i]+x;
    i = i+1;
}

Executing Vector Add Method

```java
void add(int x) {
    int i;
    i = 0;
    while (i < v.length)
        v[i] = v[i]+x;
    i = i+1;
}
```
void add(int x) {
    int i;
    i = 0;
    while (i < v.length)
        v[i] = v[i]+x;
    i = i+1;
}

Executing Vector Add Method
void add(int x) {
    int i;
    i = 0;
    while (i < v.length)
        v[i] = v[i] + x;
    i = i + 1;
}

Executing Vector Add Method
void add(int x) {
    int i;
    i = 0;
    while (i < v.length)
        v[i] = v[i]+x;
    i = i+1;
}

What does the compiler have to do to make all of this work?
Compilation Tasks

- Determine Format of Objects and Arrays
- Determine Format of Call Stack
- Generate Code to Read Values
  - this, parameters, locals, array elements, object fields
- Generate Code to Evaluate Expressions
- Generate Code to Write Values
- Generate Code for Control Constructs
Compilation Tasks

• **Determine Object Format in Memory**
  – Fields from Parent Classes
  – Fields from Current Class

• **Generate Code for Methods**
  – Field, Local Variable and Parameter Accesses
  – Method Invocations
Symbol Tables - Key Concept in Compilation

• Compiler Uses Symbol Tables to Produce
  – Object Layout in Memory
  – Code to
    • Access Object Fields
    • Access Local Variables
    • Access Parameters
    • Invoke Methods
Symbol Tables During Translation From Parse Tree to IR

- Symbol Tables Map Identifiers (strings) to Descriptors (information about identifiers)

- Basic Operation: Lookup
  - Given A String, find Descriptor
  - Typical Implementation: Hash Table

- Examples
  - Given a class name, find class descriptor
  - Given variable name, find descriptor
    - local descriptor, parameter descriptor, field descriptor
Hierarchy In Symbol Tables

• Hierarchy Comes From
  – Nested Scopes - Local Scope Inside Field Scope
  – Inheritance - Child Class Inside Parent Class

• Symbol Table Hierarchy Reflects These Hierarchies

• Lookup Proceeds Up Hierarchy Until Descriptor is Found
Hierarchy in vector add Method

Symbol Table for Fields of vector Class

Symbol Table for Parameters of add

Symbol Table for Locals of add

descriptor for field v

descriptor for parameter x

descriptor for this

descriptor for local i
Lookup In vector Example

- $v[i] = v[i]+x$;
Lookup i In vector Example

- $v[i] = v[i] + x$;

- $v$ descriptor for field $v$
- $x$ descriptor for parameter $x$
- this descriptor for this
- $i$ descriptor for local $i$
Lookup i In vector Example

- $v[i] = v[i] + x$;

- $v$ descriptor for field $v$
- $x$ descriptor for parameter $x$
- $this$ descriptor for $this$
- $i$ descriptor for local $i$
Lookup x In vector Example

- \( v[i] = v[i] + x; \)

- descriptor for field \( v \)
- descriptor for parameter \( x \)
- descriptor for this
- descriptor for local \( i \)
Lookup x In vector Example

• $v[i] = v[i] + x;$

- **v**: descriptor for field $v$
- **x**: descriptor for parameter $x$
- **this**: descriptor for this
- **i**: descriptor for local $i$
• $v[i] = v[i] + x$;
Descriptors

• What do descriptors contain?
• Information used for code generation and semantic analysis
  – local descriptors - name, type, stack offset
  – field descriptors - name, type, object offset
  – method descriptors
    • signature (type of return value, receiver, and parameters)
    • reference to local symbol table
    • reference to code for method
Program Symbol Table

- Maps class names to class descriptors
- Typical Implementation: Hash Table

- vector → class descriptor for vector
- point → class descriptor for point
- cartesianPoint → class descriptor for cartesianPoint
- polarPoint → class descriptor for polarPoint
Class Descriptor

• Has Two Symbol Tables
  – Symbol Table for Methods
    • Parent Symbol Table is Symbol Table for Methods of Parent Class
  – Symbol Table for Fields
    • Parent Symbol Table is Symbol Table for Fields of Parent Class

• Reference to Descriptor of Parent Class
Field, Parameter and Local and Type Descriptors

- Field, Parameter and Local Descriptors Refer to Type Descriptors
  - Base type descriptor: int, boolean
  - Array type descriptor, which contains reference to type descriptor for array elements
  - Class descriptor

- Relatively Simple Type Descriptors
- Base Type Descriptors and Array Descriptors Stored in Type Symbol Table
Example Type Symbol Table

- int
- int []
- boolean
- boolean []
- vector []
- vector

- int descriptor
- array descriptor
- boolean descriptor
- array descriptor
- array descriptor
- class descriptor for vector
Method Descriptors

• Contain Reference to Code for Method
• Contain Reference to Local Symbol Table for Local Variables of Method
• Parent Symbol Table of Local Symbol Table is Parameter Symbol Table for Parameters of Method
Method Descriptor for add Method

- Parameter symbol table
- Field symbol table for vector class
- Local variable symbol table
- Parameter descriptor
- This descriptor
- Local descriptor

Method descriptor for add

Code for add method
Symbol Table Summary

- Program Symbol Table (Class Descriptors)
- Class Descriptors
  - Field Symbol Table (Field Descriptors)
    - Field Symbol Table for SuperClass
  - Method Symbol Table (Method Descriptors)
    - Method Symbol Table for Superclass
- Method Descriptors
  - Local Variable Symbol Table (Local Variable Descriptors)
    - Parameter Symbol Table (Parameter Descriptors)
      - Field Symbol Table of Receiver Class
- Local, Parameter and Field Descriptors
  - Type Descriptors in Type Symbol Table or Class Descriptors

Representing Code in High-Level Intermediate Representation
Basic Idea

• Move towards assembly language
• Preserve high-level structure
  – object format
  – structured control flow
  – distinction between parameters, locals and fields
• High-level abstractions of assembly language
  – load and store nodes
  – access abstract locals, parameters and fields, not memory locations directly
What is a Parse Tree?

- Parse Tree Records Results of Parse
- External nodes are terminals/tokens
- Internal nodes are non-terminals

```
class_decl ::= 'class' name '{' field_decl method_decl '}'
field_decl ::= 'int' name '[]';'
method_decl ::= 'void' name '(' param_decl ')' '{' var_decl stats '}'
```
Abstract Versus Concrete Trees

• Remember grammar hacks
  – left factoring, ambiguity elimination, precedence of binary operators
• Hacks lead to a tree that may not reflect cleanest interpretation of program
• May be more convenient to work with abstract syntax tree (roughly, parse tree from grammar before hacks)
Building IR Alternatives

• Build concrete parse tree in parser, translate to abstract syntax tree, translate to IR
• Build abstract syntax tree in parser, translate to IR
• Roll IR construction into parsing
From Abstract Syntax Trees to Symbol Tables

- Recursively Traverse Tree
- Build Up Symbol Tables As Traversal Visits Nodes
Representing Expressions

• **Expression Trees Represent Expressions**
  - Internal Nodes - Operations like +, -, etc.
  - Leaves - Load Nodes Represent Variable Accesses

• **Load Nodes**
  - ldf node for field accesses - field descriptor
    - (implicitly accesses this - could add a reference to accessed object)
  - ldl node for local variable accesses - local descriptor
  - ldp node for parameter accesses - parameter descriptor
  - lda node for array accesses
    - expression tree for array
    - expression tree for index
Example

\[ x^2 + y^2 \]

- Field descriptor for \( x \) in field symbol table for cartesianPoint class
- Field descriptor for \( y \) in field symbol table for cartesianPoint class
Example

\( \text{v[i]} + x \)

- **lda**: Local descriptor for \( i \) in local symbol table of vector add
- **ldf**: Field descriptor for \( v \) in field symbol table for vector class
- **ldl**: Local descriptor for \( x \) in parameter symbol table of vector add
- **ldp**: Parameter descriptor for \( x \) in parameter symbol table of vector add
Special Case: Array Length Operator

- len node represents length of array
  - expression tree for array
- Example: v.length

```
len
  ↓
ldf
  ↓
field descriptor for v in field symbol table for vector class
```
Representing Assignment Statements

- **Store Nodes**
  - stf for stores to fields
    - field descriptor
    - expression tree for stored value
  - stl for stores to local variables
    - local descriptor
    - expression tree for stored value
  - sta for stores to array elements
    - expression tree for array
    - expression tree for index
    - expression tree for stored value
Representing Procedure Calls

- Call statement
- Refers to method descriptor for invoked method
- Has list of parameters (this is first parameter)

```
vect.add(1)
```
$v[i] = v[i] + x$

**Example**

- `lda`: field descriptor for $v$ in field symbol table for vector class
- `ldl`: local descriptor for $i$ in local symbol table of vector add
- `ldp`: parameter descriptor for $x$ in parameter symbol table of vector add
- `sta`: local symbol table of vector add
Representing Flow of Control

• **Statement Nodes**
  – sequence node - first statement, next statement
  – if node
    • expression tree for condition
    • then statement node and else statement node
  – while node
    • expression tree for condition
    • statement node for loop body
  – return node
    • expression tree for return value
Example

while (i < v.length)
    v[i] = v[i] + x;

field descriptor for v
local descriptor for i
parameter descriptor for x

Further Complication - Inheritance

Object Extension
Inheritance Example - Point Class

class point {
    int c;
    int getColor() { return(c); }
    int distance() { return(0); }
}

Point Subclasses

class cartesianPoint extends point {
    int x, y;
    int distance() { return(x*x + y*y); }
}

class polarPoint extends point {
    int r, t;
    int distance() { return(r*r); }
    int angle() { return(t); }
}
Implementing Object Fields

- Each object is a contiguous piece of memory
- Fields from inheritance hierarchy allocated sequentially in piece of memory
- Example: polarPoint object
Point Objects

Class Info
- point
- cartesianPoint
- polarPoint
Class Descriptors for point and cartesianPoint

class descriptor for point

class descriptor for cartesianPoint

field descriptor for c

method descriptor for getColor

method descriptor for distance

field descriptor for x

field descriptor for y

method descriptor for distance

getColor

distance

x

y
Dynamic Dispatch

```java
if (x == 0) {
p = new point();
} else if (x < 0) {
p = new cartesianPoint();
} else if (x > 0) {
p = new polarPoint();
}
y = p.distance();
```

Which distance method is invoked?

- if p is a point
  return(0)
- if p is a cartesianPoint
  return(x*x + y*y)
- if p is a polarPoint
  return(r*r)
- Invoked Method Depends on Type of Receiver!
Implementing Dynamic Dispatch

- Basic Mechanism: Method Table

  - Method table for point objects:
    - `getColor` method for point
    - `distance` method for point

  - Method table for cartesianPoint objects:
    - `getColor` method for point
    - `distance` method for cartesianPoint

  - Method table for polarPoint objects:
    - `getColor` method for point
    - `distance` method for polarPoint
    - `angle` method for polarPoint
Invoking Methods

• Compiler Numbers Methods In Each Inheritance Hierarchy
  – getColor is Method 0, distance is Method 1, angle is Method 2
• Method Invocation Sites Access Corresponding Entry in Method Table
• Works For Single Inheritance Only
  – not for multiple inheritance, multiple dispatch, or interfaces
Hierarchy in Method Symbol Tables for Points

distance

getColor

distance

method descriptor for getColor

method descriptor for distance

angle

distance

method descriptor for distance

method descriptor for angle

method descriptor for distance
Lookup In Method Symbol Tables

• Starts with method table of declared class of receiver object
• Goes up class hierarchy until method found
  – point p; p = new point(); p.distance();
    • finds distance in point method symbol table
  – point p; p = new cartesianPoint(); p.distance();
    • finds distance in point method symbol table
  – cartesianPoint p; p = new cartesianPoint(); p.getColor();
    • finds getColor in point method symbol table
Static Versus Dynamic Lookup

- Static lookup done at compile time for type checking and code generation
- Dynamic lookup done when program runs to dispatch method call
- Static and dynamic lookup results may differ!
  - `point p; p = new cartesianPoint(); p.distance();`
    - Static lookup finds distance in point method table
    - Dynamic lookup invokes distance in cartesianPoint class
    - Dynamic dispatch mechanism used to make this happen
Static and Dynamic Tables

• Static Method Symbol Table
  – Used to look up method definitions at compile time
  – Index is method name
  – Lookup starts at method symbol table determined by declared type of receiver object
  – Lookup may traverse multiple symbol tables

• Dynamic Method Table
  – Used to look up method to invoke at run time
  – Index is method number
  – Lookup simply accesses a single table element
