Lecture 5: Scheduling and Binary Search Trees

Lecture Overview

• Runway reservation system
  – Definition
  – How to solve with lists

• Binary Search Trees
  – Operations

Readings

CLRS Chapter 10, 12.1-3

Runway Reservation System

• Airport with single (very busy) runway (Boston 6 → 1)

• “Reservations” for future landings

• When plane lands, it is removed from set of pending events

• Reserve req specify “requested landing time” $t$

• Add $t$ to the set if no other landings are scheduled within $k$ minutes either way. Assume that $k$ can vary.
  – else error, don’t schedule

Example

\begin{figure}[h]
\centering
\begin{tikzpicture}
\draw[->] (0,0) -- (7,0) node[anchor=north] {time (mins)};
\draw (0,0) -- (0,-0.5) node[anchor=east] {now} node[anchor=west] {37} -- (1,0) node[anchor=west] {x} -- (2,0) node[anchor=west] {41} -- (3,0) node[anchor=west] {x} -- (4,0) node[anchor=west] {46} -- (5,0) node[anchor=west] {x} -- (6,0) node[anchor=west] {49} -- (7,0) node[anchor=west] {x} -- (8,0) node[anchor=west] {56} -- (9,0) node[anchor=west] {x};
\end{tikzpicture}
\caption{Runway Reservation System Example}
\end{figure}

Let $R$ denote the reserved landing times: $R = (41, 46, 49, 56)$ and $k = 3$
Request for time: 44 not allowed (46 ∈ R)
      53 OK
      20 not allowed (already past)
      | R | = n

Goal: Run this system efficiently in $O(\lg n)$ time

Algorithm

Keep $R$ as a sorted list.

```python
init: R = []
req(t): if t < now: return "error"
for i in range (len(R)):
    if abs(t-R[i]) < k: return "error"
R.append(t)
R = sorted(R)
land: t = R[0]
    if (t != now) return error
R = R[1:] (drop R[0] from R)
```

Can we do better?

- **Sorted list**: Appending and sorting takes $\Theta(n \lg n)$ time. However, it is possible to insert new time/plane rather than append and sort but insertion takes $\Theta(n)$ time. A $k$ minute check can be done in $O(1)$ once the insertion point is found.

- **Sorted array**: It is possible to do binary search to find place to insert in $O(\lg n)$ time. Using binary search, we find the smallest $i$ such that $R[i] \geq t$, i.e., the next larger element. We then compare $R[i]$ and $R[i-1]$ against $t$. Actual insertion however requires shifting elements which requires $\Theta(n)$ time.

- **Unsorted list/array**: $k$ minute check takes $O(n)$ time.

- **Min-Heap**: It is possible to insert in $O(\lg n)$ time. However, the $k$ minute check will require $O(n)$ time.

- **Dictionary or Python Set**: Insertion is $O(1)$ time. $k$ minute check takes $\Omega(n)$ time
What if times are in whole minutes?

Large array indexed by time does the trick. This will not work for arbitrary precision time or verifying width slots for landing.

**Key Lesson:** Need fast insertion into sorted list.

### Binary Search Trees (BST)

![Binary Search Tree Diagram]

**Properties**

Each node \( x \) in the binary tree has a key \( key(x) \). Nodes other than the root have a parent \( p(x) \). Nodes may have a left child \( left(x) \) and/or a right child \( right(x) \). These are pointers unlike in a heap.

The invariant is: for any node \( x \), for all nodes \( y \) in the left subtree of \( x \), \( key(y) \leq key(x) \). For all nodes \( y \) in the right subtree of \( x \) \( key(y) \geq key(x) \).

**Insertion:** \( \text{insert}(\text{val}) \)

Follow left and right pointers till you find the position (or see the value), as illustrated in Figure 2. We can do the “within \( k = 3 \)” check for runway reservation during insertion. If you see on the path from the root an element that is within \( k = 3 \) of what you are inserting, then you interrupt the procedure, and do not insert.
Finding a value in the BST if it exists: find(val)
Follow left and right pointers until you find it or hit NIL.

Finding the minimum element in a BST: findmin()
Key is to just go left till you cannot go left anymore.

![Figure 3: Delete-Min: finds minimum and eliminates it](image)

Complexity
All operations are $O(h)$ where $h$ is height of the BST.

Finding the next larger element: next-larger(x)

Note that x is a node in the BST, not a value.

next-larger(x)

```
if right child not NIL, return minimum(right)
else y = parent(x)
while y not NIL and x = right(y)
    x = y; y = parent(y)
return(y);
```

See Fig.3 for an example. What would next-larger(find(46)) return?

New Requirement
Rank(t): How many planes are scheduled to land at times $\leq t$? The new requirement necessitates a design amendment.

Cannot solve it efficiently with what we have but can augment the BST structure.
Summarizing from Fig.5, the algorithm for augmentation is as follows:

1. Walk down tree to find desired time
2. Add in nodes that are smaller
3. Add in subtree sizes to the left

In total, this takes $O(h)$ time.

All the Python code for the Binary Search Trees discussed here are available at this
